1 Introduction

2 Literature Review and Theoretical Framework

2.1 Immigration Attitudes and Migrant Characteristics

A large literature examines how host-country populations evaluate migrants and which characteristics shape these evaluations. One central distinction in this literature is based on whether attitudes toward migrants primarily reflect individuals' own economic interests and labor-market considerations or characteristics of the migrants.

Earlier economic studies provide some evidence that labor-market considerations are associated with immigration preferences (e.g., Scheve and Slaughter, 2001; Mayda, 2006). Beyond economic self-interest, immigration attitudes have also been linked to broader fiscal, cultural, and group-related concerns (Burns and Gimpel, 2000; Dustmann and Preston, 2007; Sides and Citrin, 2007). Reviewing this literature, Hainmueller and Hopkins (2014) conclude that evidence for explanations based on individual economic self-interest is generally limited.

Experimental evidence further challenges a simple labor-market competition explanation and rather points to the importance of migrants' own characteristics. Hainmueller and Hiscox (2010) find that both high- and low-skilled natives prefer high-skilled over low-skilled immigrants. If immigration attitudes were primarily driven by competition with similarly skilled workers, preferences would be expected to differ according to respondents' own skill levels. Instead, the common preference for high-skilled immigration suggests that respondents place considerable weight on migrants' human capital and potential economic contribution. This pattern is also found in multidimensional experiments. Higher education, occupational status, employability, and language proficiency are generally associated with more favorable evaluations of migrants (Hainmueller and Hopkins, 2015; Bansak et al., 2016; Czymara and Schmidt-Catran, 2016). More recent evidence from Germany similarly shows greater willingness to accept skilled economic migrants with recognized professional qualifications, good language skills, and a definite job offer (Wolff et al., 2025). Taken together, these studies show that characteristics associated with migrants' expected labor-market integration play an important role in how they are evaluated.

Country of origin, cultural and religious background, and migration status also influence attitudes when other characteristics are held constant. Hainmueller and Hopkins (2015) find differences in evaluations across immigrants' countries of origin alongside effects of education, occupation, and English proficiency. In the European context, Bansak et al. (2016) show that preferences over asylum seekers depend jointly on country of origin, religion, employability, and vulnerability. Similar patterns emerge in Germany. Czymara and Schmidt-Catran (2016) find that acceptance varies with migrants' country of origin and reason for migration as well as their education and German-language proficiency.

These studies show that evaluations depend not only on migrants’ individual characteristics, but also on broader group-related characteristics and migration categories.

Although much of this literature focuses on attitudes and preferences toward migrants rather than beliefs about their expected outcomes, it shows that evaluations vary systematically with migrants’ observable characteristics. In line with this literature, higher human capital and stronger language proficiency may similarly serve as signals when respondents form expectations about migrants’ economic and social integration. This leads to the first hypotheses:

H1a: Holding other migrant characteristics constant, respondents expect migrants with higher human capital to achieve more favorable labor-market integration outcomes than migrants with lower human capital.

H1b: Holding other migrant characteristics constant, respondents expect migrants with higher German-language proficiency to achieve more favorable labor-market and social-integration outcomes than migrants with lower German-language proficiency.

2.2 Beliefs and Expectations about Migrant Outcomes

A growing literature shows that individuals hold systematic beliefs about immigrants and their economic and social characteristics. Much of this research examines perceptions of immigrant populations as a whole, including their size, composition, education, and employment (Sides and Citrin, 2007; Alesina et al., 2023). Respondents tend to overestimate the share of immigrants living in their country, and perceive immigrants as less educated, more unemployed, and more dependent on government transfers than they actually are. However, these perceptions may depend on which types of migrants respondents have in mind. Blinder (2015) shows that public understandings of the term “immigrant” do not necessarily correspond to the full migrant population, with some migrant categories being considerably more salient than others. This suggests that treating migrants as a single category may obscure differences in how distinct types of migrants are perceived.

One particularly relevant distinction concerns migrants’ reasons for migration. Evaluations vary between refugees and migrants arriving for economic reasons (Czymara and Schmidt-Catran, 2016), while refugees also tend to experience less favorable actual labor-market outcomes than economic migrants, including lower employment, occupational, and earnings outcomes (Brell et al., 2020; Fasani et al., 2024). Although this evidence concerns evaluations or actual outcomes rather than beliefs about future integration, it provides reason to expect that host-country populations may also distinguish between otherwise comparable refugees and economic migrants when forming such expectations. This leads to the following hypothesis:

H2: Holding all other migrant characteristics constant, respondents expect refugees to achieve less favorable labor-market integration outcomes than economic migrants.

A related literature examines migrants’ employability and labor-market experiences and shows that employment outcomes depend not only on migrants’ individual characteristics, but also on organizational and institutional factors in the host country (Shirmohammadi et al., 2019; Farashah et al., 2023). Research on immigrant recruitment further demonstrates that employers’ perceptions can shape migrants’ employment opportunities and that migrant workers may face discrimination and disadvantages in hiring and occupational outcomes (Almeida et al., 2015; Dietz et al., 2015). However, this literature primarily examines migrants’ actual labor-market experiences or employers’ recruitment decisions rather than expectations held by the broader host-country population.

A smaller literature comes closer to examining such expectations from the perspective of the host-country population. Niemann et al. (2024), for example, study how working adults in Germany form expectations about migrants’ occupational future and integration efforts depending on migrant characteristics such as origin, skill level, and reason for migration. Related research demonstrates that individuals also hold beliefs about discrimination. Haaland and Roth (2023) document substantial heterogeneity in beliefs about racial discrimination in hiring in the United States. Although their study concerns racial discrimination rather than migration, it demonstrates the conceptual distinction between beliefs about discrimination and actual discriminatory behavior.

Taken together, existing research provides evidence on several individual dimensions of migrants’ expected integration, but evidence examining expectations across multiple economic and social outcomes remains limited. This thesis contributes to this literature by examining expectations concerning employment, occupational match, income, discrimination, and social integration for Ukrainian and Syrian refugee migrants and economic migrants in Germany.

2.3 Differential Perceptions of Ukrainian and Syrian Migrants

Earlier literature shows that responses to refugees in Germany already differed across groups and changed over time during and after the 2015–2016 refugee inflow. In particular, country of origin was associated with differences in acceptance of refugees, while other characteristics such as migration circumstances and family composition also shaped public responses (Bansak et al., 2016; Czymara and Schmidt-Catran, 2016, 2017; Plener et al., 2017; Liebe et al., 2018). Czymara and Schmidt-Catran (2017), for example, show that following the events of New Year’s Eve 2015/2016, the acceptance of refugees generally increased, whereas the acceptance of immigrants of North African and Arab origin declined. Other research demonstrates that attitudes also varied with local exposure to the refugee inflow. Albarosa and Elsner (2023), for instance, document heterogeneous changes in attitudes across German regions depending on the size of the local refugee inflow. Looking at a later period, Przechomski et al. (2026) find that, after an initial increase in negative sentiment, attitudes gradually became more positive between 2017 and 2021.

The arrival of Ukrainian refugees following Russia’s invasion of Ukraine in 2022 provided a new context for examining differences in responses to refugee groups in Europe. Existing research demonstrates that Ukrainian refugees have generally received more favorable public and institutional responses than Syrian refugees (Moise et al., 2024; Drewski and Gerhards, 2025; Das, 2025). Evidence from Germany similarly shows greater willingness to help Ukrainian refugees, more positive perceptions of their warmth and integration prospects, and greater solidarity toward them than toward Syrian refugees (Echterhoff et al., 2023; Schmidt et al., 2024; Stefaniak et al., 2025). These findings therefore suggest that public responses are shaped not only by refugee status itself but also by refugees’ country of origin.

Several explanations have been proposed for these differences. Theories of group position and perceived group threat suggest that attitudes toward immigrant groups depend partly on how these groups are positioned and perceived relative to the host population. Building on the group-position perspective of Blumer (1958), Quillian (1995) argues that prejudice can reflect perceived collective threat and the relative position of the in-group and out-group. In the context of Ukrainian and Syrian migrants, existing studies similarly point to differences in perceived cultural similarity, threat, and deservingness (Echterhoff et al., 2023; Schmidt et al., 2024; Stefaniak et al., 2025). At the broader political level, Drewski and Gerhards (2025) show that Syrian and Ukrainian refugees were framed differently in Germany and Poland and link these differences to cultural and geopolitical factors that shaped state responses to the two groups.

These findings provide reason to expect that these differences between Ukrainian and Syrian migrants may also be reflected in beliefs about their integration outcomes. In line with this literature, I develop the following hypothesis:

H3a: Holding other migrant characteristics constant, respondents expect Ukrainian migrants to achieve more favorable labor-market and social integration outcomes than Syrian migrants.

In addition, the previous discussion in Section 2.2 provides reason to expect that individuals also form beliefs about the discrimination in labor-market outcomes of migrants. Combined with the less favorable perceptions of Syrian relative to Ukrainian migrants documented in this section, I developed the following hypothesis:

H3b: Holding other migrant characteristics constant, respondents expect Syrian migrants to face greater discrimination in the German labor market than Ukrainian migrants.

Further, I am interested in whether the difference between Ukrainian and Syrian migrants may depend on their reason for migration. Much of the literature above discussing differential responses toward the two groups concerns refugees specifically. Much of the literature above discussing differential responses toward the two groups concerns refugees specifically, suggesting that country of origin may be particularly consequential when migrants are evaluated in a refugee context. By contrast, evaluations of economic migrants

may place relatively greater weight on characteristics related to their expected economic contribution. I therefore develop the following hypothesis:

H3c: The difference in expected integration outcomes between Ukrainian and Syrian migrants is greater when migrants are presented as refugees than when they are presented as economic migrants.

In addition, I explore whether differences between Ukrainian and Syrian migrants vary with their level of human capital, and in particular whether higher human capital reduces the country-of-origin gap in expected integration outcomes.

2.4 Belief Formation Through Contact, Experience, Information, and Memory

Intergroup contact is one potential source from which individuals form perceptions of migrant groups. The contact hypothesis, originating with Allport (1954), proposes that contact between members of different groups can reduce prejudice under optimal contact conditions. A large subsequent literature generally finds an association between intergroup contact and lower prejudice, with Pettigrew and Tropp (2006) showing that these effects are not limited to situations in which all of Allport’s original conditions are satisfied. Evidence from migration and refugee contexts similarly shows that direct contact is associated with more favorable evaluations of migrants and refugees (Kotzur et al., 2019; De Coninck et al., 2021; Khalil and Naumann, 2022).

However, the amount of contact alone may not capture how intergroup experiences relate to perceptions. Contact can generate both positive and negative experiences, making it important to distinguish the frequency of contact from its valence. Positive contact is generally associated with more favorable attitudes toward migrants and refugees, whereas negative contact is associated with less favorable attitudes and behavioral tendencies (Laurence and Bentley, 2018; Kotzur et al., 2019; Bagci et al., 2023). De Coninck et al. (2021) similarly distinguish between the frequency and valence of intergroup contact and find that contact valence is particularly important for attitudes toward refugees. Moreover, increased exposure does not necessarily produce more favorable responses (Enos, 2019; Hangartner et al., 2019). Taken together, this literature suggests that the nature of respondents’ experiences with migrant groups may be more informative than exposure alone. I therefore develop the following hypothesis:

H4a: Conditional on contact frequency, more positive overall personal experiences with a migrant group are associated with more favorable beliefs about that group’s integration outcomes.

The importance of contact valence is consistent with a broader literature showing that personal social experiences can shape subsequent beliefs and behavior. Schwerter and

Zimmermann (2020) experimentally show that positive and negative social experiences lead to substantial differences in subsequent willingness to trust, with beliefs about others' trustworthiness playing an important role in these effects. However, the valence of contact may also matter asymmetrically. In the intergroup-contact literature, Paolini et al. (2024) provide evidence that negative contact is more strongly associated with increased prejudice than positive contact is with reduced prejudice. Building on this evidence, I expect a similar asymmetry in the relationship between personal experiences with migrant groups and beliefs about their integration outcomes. This leads to the following hypothesis:

H4b: Negative personal experiences with a migrant group are more strongly associated with unfavorable beliefs about that group's integration outcomes than positive personal experiences are associated with favorable beliefs.

Personal experiences, however, are not the only source of information from which individuals may form beliefs about migrant groups. Experimental evidence shows that information about immigrants and refugees can influence subsequent perceptions and attitudes, although the direction and magnitude of these effects depend on the information provided and respondents' prior beliefs (Hayo and Neumeier, 2023; Dylong and Uebelmesser, 2026; Guenther, 2024). Media constitute a particularly important source of such information, providing indirect exposure to migrant groups even in the absence of direct personal contact (Schiappa et al., 2005; De Coninck et al., 2021). As with personal contact, the relationship between media exposure and attitudes may depend not only on the amount of exposure but also on its content and framing, as media representations of immigrants and refugees differ systematically in the economic, cultural, or security-related threats they emphasize (Atwell Seate and Mastro, 2016; Jacobs et al., 2016). Moreover, media exposure may itself be selective, as individuals may choose refugee-related media content based on their existing views (Lueders et al., 2019). Therefore, similar to the hypothesis about contact valence (H4a), I develop the following hypothesis:

H5: Conditional on media-exposure frequency, more positive overall media information concerning a migrant group is associated with more favorable beliefs about that group's integration outcomes.

Finally, past experiences and information may not receive equal weight when individuals form current beliefs. Models of associative memory suggest that recall is selective and cue-dependent, such that experiences related to the current context are more likely to come to mind and influence beliefs (Bordalo et al., 2023; Enke et al., 2024). Consistent with this mechanism, Graeber et al. (2024) further show that stories are more readily recalled than statistical information and consequently remain more influential on beliefs over time. Applied to the migration context, beliefs about Ukrainian and Syrian migrants may therefore depend not only on respondents' overall exposure to and experiences with each group, but also on the personal experiences and media information that are especially memorable and on the valence of these memories. This leads to my last hypotheses:

H6a: Conditional on contact frequency and overall experience valence, the valence of respondents' most memorable personal experience with a migrant group is associated with beliefs about that group's integration outcomes.

H6b: Conditional on media-exposure frequency and overall media valence, the valence of respondents' most memorable media information about a migrant group is associated with beliefs about that group's integration outcomes.

3 Experimental Design

This thesis proposes a survey experiment to examine how Germans form beliefs about the labor-market and social integration outcomes of Ukrainian and Syrian migrants. The proposed study consists of a factorial vignette experiment, a set of outcome measures, and a respondent questionnaire. The following sections describe each part of the proposed experimental design and the survey procedure.

3.1 Target Population and Proposed Sample

The target population consists of German citizens aged 18 or older who currently reside in Germany. Restricting eligibility to German citizens provides a clear operational definition of the German population whose beliefs about the integration of Ukrainian and Syrian migrants are the focus of this study. Similar citizenship-based sampling criteria have been used in previous studies examining attitudes toward refugees and migration in Germany (e.g., Hayo and Neumeier, 2023). Importantly, German citizenship is not used as a proxy for being native-born or having no migration background. Naturalized German citizens are therefore included in the target population, while respondents' migration background is collected separately as a demographic characteristic in the respondent questionnaire. At the beginning of the survey, respondents would therefore be screened with respect to age, country of residence, and German citizenship. Respondents who do not satisfy these eligibility criteria would not proceed to the experimental part of the survey.

I propose using Qualtrics to program the survey, and the online panel provider Bilendi for the recruitment of participants. Bilendi is suitable for the present study because it provides access to a large and diverse pool of respondents in Germany and allows the use of demographic quotas to approximate the composition of the target population. The proposed sample would use quotas for age, gender, education, and region. Respondents would receive compensation for their participation according to the standard compensation provided by the panel, taking into account the expected duration of the survey.

The final sample size would be determined based on a power analysis of the proposed experimental design. The number of vignette evaluations per respondent, which also affects the required sample size, is discussed in Section 3.2.

3.2 Factorial Vignette Design

The study employs a factorial vignette experiment in which respondents evaluate hypothetical migrants whose characteristics are independently varied across profiles. This approach is particularly suitable for the present research question because migrants differ simultaneously along several characteristics. By independently varying these characteristics, the design makes it possible to distinguish their effects on respondents' beliefs while holding the remaining characteristics constant. The proposed design builds on previous conjoint and factorial vignette experiments examining how migrant characteristics shape evaluations (Hainmueller and Hopkins, 2015; Bansak et al., 2016; Czymara and Schmidt-Catran, 2016).

The proposed vignettes describe migrants who have come to Germany and are currently looking for stable employment. Each profile varies independently along five binary dimensions: gender, country of origin, reason for migration, human capital, and German-language proficiency. These vignette attributes are selected to capture migrant characteristics that are central to the research questions and that previous research has shown to influence perceptions of migrants. Country of origin is varied between (1) Ukrainian and (2) Syrian migrants and represents the central comparison of the study. Reason for migration distinguishes between the two types of migrants: (1) refugees who fled the wars in Ukraine or Syria and (2) economic migrants who came to Germany in search of better employment opportunities. Educational attainment captures differences in migrants' human capital, which previous vignette and conjoint studies have shown to influence evaluations of immigrants (Hainmueller and Hiscox, 2010; Hainmueller and Hopkins, 2015; Czymara and Schmidt-Catran, 2016). The design distinguishes between (1) migrants without a formal vocational qualification and (2) migrants with a university degree. German-language proficiency is varied between (1) limited and (2) good German skills. Language proficiency may be relevant both for social integration and for labor-market outcomes, since knowledge of the host-country language represents an important form of human capital (Czymara and Schmidt-Catran, 2016). Finally, gender distinguishes between (1) male and (2) female migrants. Gender is included because previous experimental research suggests that migrant gender can affect how immigrants and refugees are perceived, including in the German context (Czymara and Schmidt-Catran, 2017; Gereke et al., 2020). Randomizing gender therefore allows the effects of the other vignette characteristics to be estimated across both male and female migrant profiles.

As discussed previously, existing research shows that religion and perceived cultural distance can influence attitudes toward immigrants (e.g., Czymara and Schmidt-Catran, 2016). However, in this study, religious affiliation is deliberately left unspecified. The main interest of this thesis is in the overall beliefs that respondents associate with Ukrainian and Syrian migrants. Explicitly including religion as an additional vignette attribute would not only make the design more complex, but could also change the beliefs that respondents would otherwise associate with the migrant's country of origin. For this reason, religion

is not varied separately in the experiment. The estimated country-of-origin effect should therefore be interpreted as an overall effect of Ukrainian versus Syrian origin, which may also reflect perceived cultural or religious differences between the two groups.

Table 1 summarizes the five vignette attributes and their respective levels and shows how the randomized characteristics relate to the hypotheses developed in Chapter 2.

Table 1: Vignette Attributes and Attribute Levels

Vignette attribute	Level 1	Level 2	Hypothesis
Country of origin	Syria	Ukraine	H3a, H3b, H3c
Reason for migration	Economic migrant	War refugee	H2, H3c
Human capital	No formal vocational qualification	University degree	H1a
German-language proficiency	Limited	Good	H1b
Gender	Male	Female	—

Notes: The table presents the five independently randomized attributes used to construct the migrant profiles. Gender is included as an additional randomized characteristic but is not associated with a separate hypothesis.

The five binary attributes generate a full factorial design of $2^5 = 32$ possible migrant profiles. The vignettes would be worded as follows:

[Mr./Mrs.] [random letter]. came to Germany from [Ukraine/Syria]. [He/She] came to Germany as [a refugee after fleeing the war in his/her country / an economic migrant in search of better employment and economic opportunities in Germany]. [He/She] [has no formal vocational qualification / has completed a university degree], speaks German [only to a limited extent / well], and is currently looking for stable employment.

Since evaluating all possible profiles would place a substantial burden on respondents, I propose that each respondent evaluate a randomly selected subset of six vignettes. This provides several profile evaluations per respondent while keeping the survey manageable, particularly because each vignette is followed by several belief questions about migrant outcomes. The choice therefore reflects a trade-off between obtaining sufficient statistical information and limiting cognitive burden and respondent fatigue, which are important considerations in factorial survey designs (Sauer et al., 2011). The exact number of vignettes could be further assessed through pilot testing prior to implementation.

3.3 Outcomes Measures

3.4 Respondent Questionnaire

3.5 Randomization and Survey Procedure

4 Empirical Strategy and Identification

- i indexes respondents.
- j indexes vignette profiles.
- $g \in \{\text{Ukraine, Syria}\}$ indexes migrant groups.
- Y_{ij} denotes respondent i 's evaluation of vignette j .
- C_{ig} denotes respondent i 's contact exposure to migrant group g .
- Q_{ig} denotes respondent i 's overall contact quality with migrant group g .
- M_{ig} denotes respondent i 's media exposure regarding migrant group g .

General Notation: For inline equations, use For displayed equations, use

...

or the equation environment.

1. Explained vignette attributes: *Origin_j MigrationStatus_j Gender_j Education_j GermanSkills_j*

Citing measurement sources for the respondent questionnaire: C_{ig}^{Work} workplace contact frequency C_{ig}^{Social} social contact frequency Q_{ig} contact quality

Contact quality: The notation $Q_{ig} \in \{1, \dots, 7\}$ denotes respondent i 's overall contact quality with migrant group g . Contact quality is measured on a 7-point scale, where 1 indicates very negative contact experiences and 7 indicates very positive contact experiences. The measure is adapted to distinguish between the two origin groups examined in the present study.

$$PositiveExperience_{ig} = \max(Q_{ig} - 4, 0)$$

$$NegativeExperience_{ig} = \max(4 - Q_{ig}, 0)$$

Following the intergroup-contact literature, the questionnaire distinguishes between the frequency and quality of respondents' contact with members of the two origin groups. This distinction is motivated by previous evidence showing that the quantity and valence of intergroup contact constitute conceptually distinct dimensions and may have different

relationships with attitudes toward refugees (e.g., De Coninck et al., 2021). Contact is measured separately for Ukrainians and Syrians and across workplace and non-work social settings.

Media exposure: $MediaExposure_{ig}$ Media exposure is measured separately for Ukrainian and Syrian refugees. Building on work conceptualizing refugee-related media exposure as a form of indirect intergroup contact (e.g., De Coninck et al., 2021), respondents report the frequency with which they encounter relevant news and media coverage. The measure is adapted to distinguish between the two origin groups examined in the present study.

Motivated by research showing that the memorability of information and narratives may influence subsequent beliefs (Graeber et al., 2024), the questionnaire additionally elicits whether respondents can recall a particularly salient personal experience involving members of either origin group and, if so, the valence of that experience.

Belief about migrant integration:

Beliefs about large communities and network effects:

Large community $\rightarrow$ More information/referrals $\rightarrow$ Better employment
versus

Large community $\rightarrow$ Less native interaction $\rightarrow$ Slower integration.

Construct:

$$\Delta B_i^{\text{Network}} = B_{i,S}^{\text{Network}} - B_{i,U}^{\text{Network}}$$

Identification and equations: Baseline equation:

$$Y_{ij} = \alpha + \beta_1 Ukr_j + \beta_2 Ref_j + \beta_3 Female_j + \beta_4 HighSkill_j + \beta_5 German_j + \varepsilon_{ij}.$$

Adjusted specification:

$$Y_{ij} = \alpha + \beta_1 Ukr_j + \beta_2 Ref_j + \beta_3 Female_j + \beta_4 HighSkill_j + \beta_5 German_j + \delta' \mathbf{X}_i + \varepsilon_{ij}.$$

H4 regression with interaction term:

$$Y_{ij} = \alpha + \beta_1 Ukraine_j + \beta_2 Refugee_j + \beta_3 (Ukraine_j \times Refugee_j) + \gamma' \mathbf{Z}_j + \varepsilon_{ij}.$$

where

$$\mathbf{Z}_j = \begin{pmatrix} Female_j \\ HighSkill_j \\ GoodGerman_j \end{pmatrix}$$

$$\mathbf{X}_i = (Age_i, Gender_i, Edu_i, Emp_i, Inc_i, Mig_i, East_i, Religion_i, Right_i)'$$

Then,

$$Y_{ij} = \alpha + \boldsymbol{\beta}'\mathbf{Z}_j + \boldsymbol{\theta}'\mathbf{X}_i + \varepsilon_{ij},$$

where $\boldsymbol{\theta}$ is the vector of coefficients associated with the respondent controls, and $\mathbf{Z}_j$ is contains the randomized vignette characteristics and $\mathbf{X}_i$ contains respondent-level controls.
